

Understanding Your Risk Rating

All infrared breast examinations are placed in a specific TH (thermobiological) risk category. Your risk of future breast cancer, and the chance that a cancerous tumor is present, increases with higher TH ratings.

TH 1 – Normal Non-Vascular Image

- Normal with minimal risk of cancer.
- When compared to each other, both breasts are even in temperature and cool (dark colors).

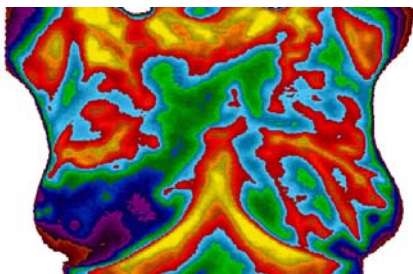

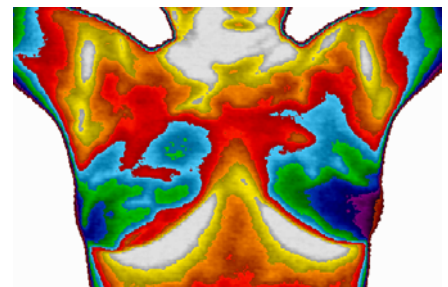

TH 2 – Normal Vascular Image

- Normal with minimal risk of cancer.
- Evenly distributed areas of heat (blood vessels) in both breasts.
- If present, specific vascular patterns may indicate increased estrogen activity.

TH 3 – Equivocal Image (questionable)

- Classified between normal and abnormal.
- One breast with a single thermovascular finding.
- Early follow-up infrared examination is indicated to monitor the stability and/or possible progression of any noted regions of interest.

TH 4 – Abnormal Image

- Abnormal with a higher possibility that cancer is present.
- More aggressive heating (blood vessels) in one breast vs. the other.
- Higher risk of future breast cancer when other tests are negative.
- Early follow-up infrared examination is indicated.

TH 5 – Severely Abnormal Image

- Severely abnormal with a higher possibility that cancer is present.
- Highly aggressive heating (blood vessels) in one breast vs. the other.
- Higher risk of future breast cancer when other tests are negative.
- Early follow-up infrared examination is indicated.
